Abstract.

The microstructures and microwave dielectric properties of barium cobalt zinc niobate ceramics prepared by conventional mixed oxide route have been investigated. It was found that low levels doping of V$_2$O$_5$ (up to 0.2 wt%) can significantly improve densification of the specimens and their properties. Dielectric properties of V$_2$O$_5$ doped samples were affected by 1:2 ordering in the B-site. Slow cooling after sintering or annealing in a nitrogen atmosphere improved the unloaded quality factor (Q.f values) significantly. The Ba$_3$Co$_{0.7}$Zn$_{0.3}$Nb$_2$O$_9$ (BCZN) ceramics exhibited $\varepsilon_r = 34.5$, $\tau_f = 0$ ppm/C and Q.f = 85000 at 4GHz.

Introduction.

Ceramic dielectrics have been extensively used for microwave communication systems. The advantage of using microwave dielectric ceramics is the size reduction of microwave components. Requirements for these dielectric materials must be the combined dielectric properties of a high dielectric constant ($\varepsilon_r$), low dielectric loss (high Q.f value) and a near-zero temperature coefficient of resonant frequency ($\tau_f$). These three parameters are related to the size, frequency selectivity and temperature stability of the system, respectively. To satisfy the demands of microwave circuit designs, each dielectric property should be precisely controlled. Several complex perovskites ceramics A(B$^{1/3}$B$^{2/3}$)O$_3$ are been known for their excellent microwave dielectric properties. Among these materials, Ba$_3$Co$_{0.7}$Zn$_{0.3}$Nb$_2$O$_9$ possesses a high dielectric constant ($\varepsilon_r \sim 34.5$), a high quality factor (Q.f 56000 to 85000 GHz) and small temperature coefficient of resonant frequency ($\tau_f \sim 0$)[1,2,3].
In this study we investigate the effect of V$_2$O$_5$ on the sintering behaviour, cation order and microwave dielectric properties, particularly the Q.f values of Ba$_3$Co$_{0.7}$Zn$_{0.3}$Nb$_2$O$_9$ ceramics.

**Experimental.**

Specimens were prepared by a conventional mixed oxide route. High purity (>99.9%) BaCO$_3$, ZnO, Nb$_2$O$_5$ and V$_2$O$_5$ were used as raw materials. The powders were weighed according to the composition Ba$_3$Co$_{0.7}$Zn$_{0.3}$Nb$_2$O$_9$ + 7.5 wt%Ba$_8$Zn$_1$Nb$_6$O$_{24}$. They were mixed in propan-2-ol with zirconia media for 18h, calcined at 1100°C for 4h, then V$_2$O$_5$ was added and wet milled for 18h and dried. Pellets were formed by pressing powders in steel dies (20mm diameter) at a pressure of 100MPa. These were sintered at 1450°C for 4h in air and cooled at 60°C/hour. Selected compositions were annealed in a nitrogen atmosphere at 1360°C for up to 10 hours. The final dimensions of these specimens were approximately 15.5mm diameter and 9mm thick.

Microstructural observation of the sintered ceramics was performed by means of SEM (Philips XL30). The sintered surfaces of ceramics were ground (to 1200 grade SiC) and polished (to 1µm diamond paste). The samples were then coated with carbon prior to SEM analysis.

The crystal structures were examined by XRD (Philips Analytical, X’pert-MPD) employing CuK$_{a1}$ radiation under the conditions 50kV and 40mA. The samples were scanned at 0.04°intervals of 2θ in the range 10-70°; the scan rate was 0.01°2θ/sec.

TEM specimens were prepared from the sintered ceramics, after lapping and polishing to form 3mm diameter discs. The discs were dimpled to 30µm thickness in the centre and then thinned to electron transparency with a Gatan Precision Ion Polishing System. The specimens were investigated using a Tecnai G2 TEM operating at 300kV.
The dielectric properties were measured by the parallel plate method[4]. The \( \tau_f \) measurements were performed using a silver plated aluminium cavity at temperatures between –10 and +60°C.

**Results.**

Figure 1 shows the bulk densities of BCZN ceramics. It can be seen that the addition of \( \text{V}_2\text{O}_5 \) promoted densification. A similar trend was observed (Figure 2) for the Q.f values of the samples. Figure 3 shows the XRD spectrum of samples prepared with 0.025 wt% \( \text{V}_2\text{O}_5 \). The pattern shows the characteristics of a 1:2 ordered hexagonal structure with the presence of the superstructure reflection at \( 2\theta =17.6^\circ \). An extra peak were observed at \( 2\theta =29.6^\circ \) which is associated with the formation of the \( \text{Ba}_8\text{Zn}_1\text{Nb}_6\text{O}_{24} \) phase.

The increase in the Q.f values is a result of the combined effect of the increase in density, structural homogenisation at atomic levels and Zn, Co and Nb ordering on the B-sites. These changes have been achieved by a liquid phase mechanism through the additions of vanadium oxide.

The dielectric constants and \( \tau_f \) values of the dense samples were not significantly affected by \( \text{V}_2\text{O}_5 \) additions and were \( \approx 34.5 \) and \( \approx 0 \) ppm/°C respectively. Further enhancement of the quality factor of the ceramics was achieved by annealing in a nitrogen atmosphere at temperatures below the order-disorder transition (Figure 4). XRD examinations showed that The increase in the degree of B-site ordering is the main factor for the enhancement in the Q.f values.

The formation of the \( \text{Ba}_8\text{Zn}_1\text{Nb}_6\text{O}_{24} \) phase was confirmed by SEM and TEM examination. Figure 5 shows bright field TEM image of the above sample. The \( \text{Ba}_8\text{Zn}_1\text{Nb}_6\text{O}_{24} \) phase appeared as elongated needle shape grains in the microstructure. The presence of structural modulations can be seen in the grains of this phase. This phase was observed at the grain
boundaries as well as within BCZN grains. Figure 6 shows a high resolution TEM image of a single domain. The grain is viewed along <011> type zone axis of the cubic unit cell.

Conclusions.

High density with a high degree of 1:2 order in BCZN ceramics were achieved by additions of vanadium oxide. BCZN ceramics prepared with 0.025 wt% V$_2$O$_5$ additions sintered at 1450°C for 4 hours and annealed in nitrogen atmosphere possessed excellent microwave dielectric properties: $\varepsilon_r \sim 34.5$, Q.f value $\sim$85000 at 4GHz and $\tau_f$ of close to zero.
